INTRODUCTION

Ten millions of fish are killed every year by a wide variety of different pollutants from many sources like municipal, agricultural and industrial. From industrial and agricultural operations, these compounds find their way into the natural water resources and affect the aquatic organism (Tilak et al., 2007). Some toxicants contained in the industrial effluents have been reported to be toxic, depending on the dose and exposure duration (Yusuff and Sonibare, 2004), and they can impart serious damage to aquatic life (Vinodhini et al., 2009). The pollutants build up in the food chain and cause the adverse effects and finally death of aquatic organisms (Ogundiran et al., 2010). During the stress, organisms need sufficient energy which is supplied from reserve material (glycogen, lipid and protein), if the stress is mild then only stored glycogen is used as a source of energy, but when stress is strong then the energy stored in lipids and protein may be used. The heavy metals cause metabolic rearrangement in the living system. Due to their potential toxicity, biochemical changes occur in the organs of animals. (Ram and Sathyanesan, 1984).

Heavy metals have been recognized as strong biological poisons because of their persistent nature and cumulative action. (Joshi et al., 2003; Hoo et al., 2004). Heavy metals have high affinity to sulfhydryl groups and disulfide bonds which cause damage to secondary structure of proteins and alter the enzymatic activities (Siediecka and Krupa, 2002). The mechanism of action lies in their ability to form strong bonds with bases and phosphates of nucleic acids. They compete with other divalent cations and replace them in their physiological roles (Tabaldi et al., 2007). Ramasamy (1987) has studied the effects of sevin on the lipid content levels of liver and muscle of Sarotherodon mossambicus and noted lipids was accumulated. He reported that the lipid levels were much altered when fish was exposed to toxicants (Saravanan et al., 2003). Jha (1991), studied the alteration in the protein and lipid contents of intestine, liver and gonads in the lead exposed freshwater fish, Channa punctatus. (Katti and Sathyanesan, 1983) studied the lead nitrate induced changes in lipid and cholesterol level of freshwater fish, Clarius batrachu.

Dutta and Haghighi (1986) suggested that heavy metals inhibit cholesterol synthesis in fish. As a result, there is insufficient cholesterol for the maintenance of cell membranes. Cholesterol constitute the vital organic substances, playing an important role in energy metabolism, hence cholesterol from liver and gonads were studied in a freshwater teleost fish, Amblypharyngodon mola which is edible fish in North Maharashtra region. Therefore an attempt was made to study the changes in the biochemical composition in different tissues of the fish, when exposed to different heavy metals.

ABSTRACT

Effect of mercuric chloride, arsenic trioxide & cadmium chloride on total cholesterol alteration in liver and gonads of a freshwater teleost fish, Amblypharyngodon mola were studied. The fishes were exposed to 0.2291 ppm. mercuric chloride, 1.4557 ppm. Arsenic trioxide and 3.1395 ppm. Cadmium chloride as a chronic treatment. In experimental groups a progressive decrease in total cholesterol content were found with respect to exposure period in liver and gonads after chronic exposure to Mercuric chloride, Arsenic trioxide and Cadmium chloride as compared to control groups.
MATERIALS AND METHODS

Live specimens of *Amblypharyngodon mola* were collected from Girna river dams of Chalisgaon, Dist. Jalgaon (M. S.), stored in 60 litre glass aquarium containing dechlorinated water with aeration system. Animals were acclimated to laboratory conditions for 10 days. During the experiment healthy fishes of uniform size and weight were selected for the experiment. Fishes were divided into two groups; one group was maintained as control while the remaining one was separately exposed to the chronic treatment. For chronic treatments the experimental groups of fishes were exposed to 0.2911 ppm Mercuric chloride, 1.4557 ppm Arsenic trioxide and 3.1395 ppm Cadmium chloride (LC50/10 values of 96 hours) up to 21 days. At the end of 7, 14 and 21 days of treatment, the control and experimental fishes were sacrificed by decapitation method, liver and gonads were gently separated; used for estimation of their cholesterol in contents. The total cholesterol contents were estimated by using Knobil method. (Knobil et al., 1954). The amount of cholesterol contents was expressed in terms of cholesterol /100 mg. of wet wt. of tissue, each observation was confirmed by taking at least five replicates. The differences in control and experimental animals groups was tested for significance by ‘t’ test (Bailey, 1965) and the percentage decreased or increased over control was calculated for each value.

RESULTS

The depletion in cholesterol contents in all tissues after chronic heavy metals stress were increased as the period of exposure increased. The maximum depletion occurred in the liver followed by gonads. A comparative study showed that the gradual decrease in cholesterol content in various tissues of freshwater teleoset fish, *Amblypharyngodon mola* after chronic treatment of heavy metals for various periods of exposure as compared to control. The results are summarised in table-1. The results are also demonstrated that the order of heavy metal effect in cholesterol content in tissues of liver and gonads of *Amblypharyngodon mola*, after chronic exposure, were found that the depletion were more in Mercuric chloride (HgCl2) later on in the Arsenic trioxide (As2O3) and then in to the Cadmium chloride (Cdcl2) as compared to control.

DISCUSSION

Amudha P. et al. (2002) studied the Dairy effluent induced alterations in the protein, carbohydrate and lipid metabolism of a freshwater teleoset fish, *Oreochromis massambicas*, who found that, these concentrations decrease depending on the dose of the effluent. According to Ramana Rao and Ramamurthi (1980), the increase in activity of enzymes lipase is for increasing lypolytic activity to meet the increased demand of energy during stress. Shivaprasad Rao and Ramana Rao (1979), studied that considerable decrease in total lipids in tissue might be due to drastic decrease in glycogen content in the same tissue which is an immediate source of energy during toxic stress condition. After glycogen, lipid content may be used for energy production to overcome toxic stress condition. Some workers support the results in which lipid content decreases. Copuzzo and Lanacaster (1981), reported significant decrease in lipid of post larval lobster when exposed to pollutants. A decrease in total lipid content in tissue reported by Ram and Sathyanesan (1984) on *Channa punctatus* intoxicated with mercuric chloride. The loss of the lipid may be a consequence of inhibition of lipid synthesis and mobilization of stored lipids, Mani and Saxena (1985).

In the present investigation lowering in liver and gonads cholesterol in fresh water teleoset fish, *Amblypharyngodon mola*, to an increase in lipid utilization to meet additional energy requirements under stress condition. Lipids may be mobilized to meet the energy requirement of fish either through oxidation or a process of gradual instauration of lipid molecules. In the present work considerable decrease in total lipids in tissue might be due to drastic decrease in glycogen content in the same tissue which is an immediate source of energy during toxic stress condition, significant depletion in cholesterol contents were observed. Similar findings noted by a significant depletion in liver cholesterol content have been reported after Cd treatment of *Garra mullya* for four months (Sinha et al., 2001). Sindhe et al. (2002) also reported a decline in cholesterol of both the liver and ovary of *N. notopterus* after exposure to Cd and Hg for two months. Lowering of cholesterol may be attributed to an increase in lipid utilization.

### Table 1: Impact of heavy metals Mercuric chloride (HgCl2), Arsenic trioxide (As2O3) and Cadmium chloride (Cdcl2) on Cholesterol content in liver and gonads of *Amblypharyngodon mola* after chronic treatment

Values expressed as mg/100 mg of wet wt. of tissue; (+) or (-) indicate percent variation over control; + indicate S.D. of liver observations; Values are significant at P<0.001***
for meeting additional energy requirements under stress conditions, as suggested by Srivastava et al. (2002). The reduction in hepatic and ovarian cholesterol content may also result in altered vitellogenesis and steroidogenesis, as suggested by Sindhe et al. (2002) in *N. notopterus*.

The present investigation concluded that the depletion in the metabolites indicates the fact that whole metabolic pool of the fish gets disturbed / altered under the toxic stress. Further, the change in the biochemical profile indicates their rapid utilization to provide excess energy to cellular biochemical process in order to cope with the stressful condition. The investigatory results of comparative study showed that decrease in cholesterol in liver and gonads were more in mercuric chloride treatment as compared to Arsenic trioxide and decrease in cholesterol in liver and gonads were more in arsenic trioxide as compared to Cadmium chloride as compared to control.

REFERENCES

be distinguished in the text and in the references by letter arranged alphabetically followed by the citation of the years eg. 2004a, 2004b.

Standard abbreviations and units should be used, SI units are recommended. Abbreviations should be defined at first appearance and their use in the title and abstract should be avoided. Generic names of chemical should be used. Genus and species names should be typed in italics.

**PROOFS AND REPRINTS**

Page proofs will be sent by e-mail to the corresponding author. The corrected proofs should be returned to the Executive Editor within 7 days of receipt. The delay in sending the proofs may shift the paper of the next issue. Correspondence through e-mail will be preferred to avoid delay.

No gratis reprints are supplied. Authors have to purchase 25 or a multiple of it (as ordered) by paying the cost decided on the basis of number of printed pages. The paper will not be printed without proper payment of reprint cost in due time.

**MEMBERSHIP OF THE JOURNAL**

The individual membership is open only for students and authors. Others can become members of the journal by paying the institutional rates. The membership form should be neatly filled preferably in BLOCK letters. All the authors should become subscribers.

**CORRESPONDENCE**

Any correspondence regarding the manuscript should be made with Executive Editor to whom the paper has been submitted.

All correspondence regarding subscription, non-receipt of the issues etc. should be made with the managing editors.

**REMITTANCES**

All payments must be made by DD in the name of “The Bioscan” payable at Ranchi. Outstation cheques will not be accepted.

**Address for correspondence**
