INTRODUCTION

The modern system of farming, it is increasingly felt, is becoming unsustainable as evidenced by declining crop productivities, damage to environment, chemical contaminations, etc. The necessity of having an alternative agriculture method which can function in a friendly eco-system while sustaining and increasing the crop productivity is realized now. Organic farming is recognized as the best known alternative to the conventional agriculture. It is a crop production system that avoids the use of synthetic and chemical inputs like fertilizers, pesticides, growth regulators and livestock feed additives. Organic manures such as farmyard manure (FYM), cereal compost, legume compost and combination of all the manures with or without PGPR [PGPR: Plant Growth Promoting Rhizobacteria containing Rhizobium + Azotobacter + Pseudomonas + Trichoderma] was applied @ 5 t/ha in each plot. It was found that among all the manures tested for cultivation of mungbean, FYM was found to be superior having 320.91, 20.3, 286.72 kg ha⁻¹ N, P₂O₅ and K₂O respectively. The combined application of cereal compost and legume compost was effective over their sole application. Application of PGPR was beneficial showing higher nutrient content in soil. The most effective treatment was found to be FYM + PGPR among all the manures showing the highest amount of nutrients of 339.71, 22.33 and 298.66 kg ha⁻¹ N, P₂O₅ and K₂O respectively.

ABSTRACT
A field experiment was undertaken in the organic farming plot of the Institute of Agricultural Sciences, BHU, Varanasi with a view to study the effects of manures and PGPR on soil properties. Mungbean (var. Malviya 12) was grown in the plot during kharif season of 2009. Organic manures such as Farm yard manure (FYM), Cereal compost, Legume compost and combination of all the manures with or without PGPR [PGPR: Plant Growth Promoting Rhizobacteria containing Rhizobium + Azotobacter + Pseudomonas + Trichoderma] was applied @ 5 t ha⁻¹ in each plot. It was found that among all the manures tested for cultivation of mungbean, FYM was found to be superior having 320.91, 20.3, 286.72 kg ha⁻¹ N, P₂O₅ and K₂O respectively. The combination applied of cereal compost and legume compost was effective over their sole application. Application of PGPR was beneficial showing higher nutrient content in soil. The most effective treatment was found to be FYM + PGPR among all the manures showing the highest amount of nutrients of 339.71, 22.33 and 298.66 kg ha⁻¹ N, P₂O₅ and K₂O respectively.

MATERIALS AND METHODS

The field experiment was conducted at the Research Farm of the Institute of Agricultural Sciences, Banaras Hindu University, Varanasi in the organic farming plot. The treatment details were, Farm yard manure (FYM), Cereal compost, Legume compost, combination of all the manures with or without PGPR. [PGPR: Plant Growth Promoting Rhizobacteria containing Rhizobium + Azotobacter + Pseudomonas + Trichoderma], Manures were applied @ 5 t/ha. There were 30 experimental plots along with three control plots (without any organic manure application). The experiment was conducted in Randomized Block Design. Before sowing the seeds in the field, these were treated with PGPR in the laboratory. Rhizobium, Azotobacter, Pseudomonas and Trichoderma was prepared by Yeast Extract Mannitol Agar medium method,
Ashby’s Mannitol Agar medium method, Pikovskaya’s medium method and potato dextrose agar method respectively. The seeds were treated with these treatments for overnight on a day before sowing. Soil samples collected after harvesting of the crop were analyzed for pH (Jackson, 1973), EC (Jackson, 1973), organic carbon (Walkley and Black, 1934), available N (Subbiah and Asija, 1956), P (Olsen et al., 1954), K (Hanway and Heidel, 1952) and S (Chesnin & Yien, 1950) in the Soil Chemistry Laboratory of the Department of Soil Science and Agricultural Chemistry, IAS, BHU.

RESULTS AND DISCUSSION

Effect of treatments on pH and EC of soil samples

The value of pH and EC varied between 8.11 to 8.34 and 0.102 to 0.117 dS/m respectively. FYM treated soils showed lower pH and EC followed by the cereal compost treated soils without PGPR. This decrease might be due to the production of organic acids during decomposition of FYM in soil. Effects of all the manures were found to be significant over control. Cereal compost + PGPR showed highest pH (8.34) in soil among all the applications followed by the combined application of all the manures with PGPR. Among the manures application with PGPR, FYM + PGPR showed lowest pH and EC due to secretion of organic acids during decomposition of FYM. Legume compost + PGPR also showed comparatively lesser pH and higher EC than cereal compost + PGPR. The drop in pH may be attributed to the effect of inoculants on rate of organic matter degradation. Some workers reported that release of organic acids with application of PGPR decreases pH of soil sample.

Effect of PGPR on organic carbon of soil sample

Organic carbon content of soils varied from 0.48 to 0.75, Lokanath et al., (2004) found that in groundnut the initial soil test values showed 0.56 per cent organic carbon. It was evident from the table that FYM treated plots showed higher organic carbon content (0.72) than other manures without PGPR. This is in accordance with the result of Yadav et al., (2009) who reported that FYM application increases organic carbon content in soil. Lowest organic carbon was found in cereal compost treated soils. Organic carbon was higher in legume compost treated soils. Combination of both of the above manures produced higher organic carbon in soil than their sole application. Combined application of all the manures showed higher organic carbon in soil and the value was next to FYM application. All the manures were significant in their effect over control. According to Rajendra Prasad (2005), continued use of organic manure on a farm improves its organic matter content, which supports the soil micro, meso and macro fauna and makes the soil a living body.

Manure application with PGPR showed higher organic carbon in soil as compared to the sole application of manures. FYM + PGPR treated soils showed highest organic carbon in soil. Almost similar to this were the organic carbon content produced by combined application of all the manures with PGPR. It was followed by the legume compost + PGPR treated soils showing comparatively higher organic carbon content in soils in comparison to the application of cereal compost + PGPR.

Effect of treatments on available N, P and K content of soil

Available nitrogen content in soil varied from 285.38 to 339.73 kg ha⁻¹ and was in medium range. The values of P content varied between 16.36 to 22.33 kg ha⁻¹ and were in medium range. It was observed that K content in soil samples varied between 226.98 to 298.66 kg ha⁻¹ i.e. in medium to high range. Lokanath et al., (2004) found that in groundnut the initial soil test values were 270.61 kg available N ha⁻¹, 40.85 kg available P₂O₅ ha⁻¹, 436.67 kg available K₂O ha⁻¹, with 7.7 pH. Higher available nitrogen, P and K was found in FYM treated plots followed by the combined application of all the manures without PGPR. Ramesh et al., (2006) found that the soil organic carbon, available N and K were higher in cattle dung manure treatment. Legume compost treated soils contained higher N, P and K content in comparison to the cereal compost treated soils. Sangakkara (1999) reported that the impact of the microbial solution was greater, when supplied with organic matter with a low C: N ratio. But the combined application of cereal compost and legume compost showed higher nutrient content in soils in comparison to their sole application. But the effects of all the manures were found to be significant over control.

PGPR application along with manures were found to be beneficial over sole application of manures. Combined application of all the manures along with PGPR followed the

</table>
above treatments. All the manures with PGPR showed higher N, P and K content in soils in comparison to the application of manures without PGPR. But the effects of all the treatments were found to be significant over control. Thus, application of PGPR alongwith manures was superior over sole application of manures. Similar results were found when Singh and Subba Rao (1979) who found that PSB increased the available P content of the soil. Also Prasad and Chandra (2003) and Gunasekaran et al. (2004) found that PGPR also increased the available P content of the soil. Kucey et al. (1989) showed that Phosphorus biofertilizers could help increase the availability of phosphates accumulated in the soil and could enhance plant growth by increasing the efficiency of biological nitrogen fixation. Shinde et al. (2008) reported that upon application of PGPR, the available nitrogen, phosphate and potash were increased from 199.0 to 282.0, 14.77 to 27.52 respectively.

Effect of treatments on available sulphur content of soil

S content of soils varied between 22.85 to 35.98 mg kg⁻¹ (ppm) i.e. in medium to high range. Soils treated with FYM had higher S content than other manures followed by the combined application of all the manures. Cereal compost showed lesser S content in comparison to the legume compost treated soils. Sangakkara (1999) reported that the impact of the microbial solution was greater, when supplied with organic matter with a low C:N ratio. But the combined application of cereal compost and legume compost was found to be superior over their individual application. Effects of all the manures were significant over control.

Application of PGPR alongwith manures was found to be beneficial showing higher S content in soils. FYM+ PGPR showed highest S content in soils. Combination of cereal compost and legume compost + PGPR was found to be beneficial over application of cereal compost + PGPR and legume compost + PGPR. But the S content in combined application of all the manures alongwith PGPR was next to FYM + PGPR. Effects of all the manures with or without PGPR were found to be significant over control.

INSTRUCTION TO AUTHORS

The Bioscan
An International Quarterly Journal of Life Science

THE JOURNAL
The Bioscan is an international quarterly journal of life sciences with international editorial board. The journal is online and details can be seen (downloaded from the site. www.thebioscan.in). For any query e-mail at m_psinha@yahoo.com & dr.mp.sinha@gmail.com can be used.

AIM & SCOPE
The journal aims to publish original peerly reviewed/refereed research papers/reviews on all aspects of life sciences.

SUBMISSION OF MANUSCRIPT
Only original research papers are considered for publication. The authors may be asked to declare that the manuscript has not been submitted to any other journal for consideration at the same time. Two hard copies of manuscript and one soft copy, complete in all respects should be submitted. The soft copy can also be sent by e-mail as an attachment file for quick processing of the paper.

FORMAT OF MANUSCRIPT
All manuscripts must be written in English and should be typed double-spaced with wide margins on all sides of good quality A4 paper.

First page of the paper should be headed with the title page, (in capital, font size 16), the names of the authors (in capitals, font size 12) and full address of the institution where the work was carried out including e-mail address. A short running title should be given at the end of the title page and 3-5 key words or phrases for indexing.

The main portion of the paper should be divided into Abstract, Introduction, Materials and Methods, Results, Discussion (or result and discussion together), Acknowledgements (if any) References and legends.

Abstract should be limited to 200 words and convey the main points of the paper-outline, results and conclusion or the significance of the results.

Introduction should give the reasons for doing the work. Detailed review of the literature is not necessary. The introduction should preferably conclude with a final paragraph stating concisely and clearly the aims and objectives of your investigation.

Materials and Methods should include a brief technical description of the methodology adopted while a detailed description is required if the methods are new.

Results should contain observations on experiment done illustrated by tables and figures. Use well known statistical tests in preference to obscure ones.

Discussion must not recapitulate results but should relate the author’s experiments to other work on the subject and give their conclusions.

All tables and figures must be cited sequentially in the text. Figures should be abbreviated to Fig., except in the beginning of a sentence when the word Figure should be written out in full.

The figures should be drawn on a good quality tracing/white paper with black ink with the legends provided on a separate sheet. Photographs should be black and white on a glossy sheet with sufficient contrast.

References should be kept to a minimum and listed in alphabetical order. Personal communication and unpublished data should not be included in the reference list. Unpublished papers accepted for publication may be included in the list by designating the journal followed by "in press" in parentheses in the reference list. The list of reference at the end of the text should be in the following format.

References in the text should be quoted by the author's name and year in parenthesis and presented in year order. When there are more than two authors the reference should be quoted as: first author followed by et al., throughout the text. Where more than one paper with the same senior author has appeared in on year the references should be quoted by the author's name and year in parenthesis and presented in year order.
